Let X be any random variable with finite expected value and variance. Then for every positive real number a , $P(|X - E(X)| \geq a) \leq \frac{\text{Var}(X)}{a^2}$. There is a direct proof of this inequality in Grinstead and Snell (p. 305) but we can also prove it using Markov's inequality! Proof. Let $Y = (X - E(X))^2$.

Expected value and variance-covariance of generalized hyperbolic distributions. The function `mean` returns the expected value.

The function `vcov` returns the variance in the univariate case and the variance-covariance matrix in the multivariate case.

Moreover, it determines the degree to which the values of a random variable differ from the expected value.

Generally, it shows how spread are the outcomes. The variance of a random variable X is the expected value of the squared deviation from the expected value of X . As a result, it's defined with $\text{Var}X = E[(X - EX)^2]$ We

The expected value of a constant is just the constant, so for example $E(1) = 1$.

Multiplying a random variable by a constant multiplies the expected value by that constant, so $E[2X] = 2E[X]$. A useful formula, where a and b are constants, is:

random variables is conveniently quite simple to calculate.

Say we have a two random variables (X) and (Y) , and that $(E(X)=\mu_X)$ and $(E(Y)=\mu_Y)$. Now suppose we have a random variable $(Z = aX + bY + c)$.
